METHODS FOR RESETTING STALLED PUMPS IN ELECTRONICALLY CONTROLLED DISPENSING SYSTEMS

CROSS REFERENCE TO RELATED APPLICATION

This is a continuation-in-part application of application Ser. No. 12/616,798 filed Nov. 12, 2009, which is incorporated herein by reference.

TECHNICAL FIELD

The present invention is generally directed to fluid dispensing systems. In particular, the present invention is directed to dispensers which allow only designated refill containers with dispensable material to be installed therein and, if desired, installed by selected distributors. More specifically, the present invention is directed to resetting stalled pumps used in 20 electronically keyed fluid dispensing systems.

BACKGROUND ART

It is well known to provide fluid dispensers for use in 25 restaurants, factories, hospitals, bathrooms and the home. These dispensers may contain fluids such as soap, anti-bacterial cleansers, disinfectants, lotions and the like. It is also known to provide dispensers with some type of pump actuation mechanism wherein the user pushes or pulls a lever to 30 dispense a quantity of fluid into the user's hands. "Handsfree" dispensers may also be utilized wherein the user simply places their hand underneath a sensor maintained by a dispenser housing and a quantity of fluid is dispensed by a motorized pump. Related types of dispensers may be used to 35 dispense powder, aerosol materials or paper products.

Dispensers may directly hold a quantity of fluid, but these have been found to be messy and difficult to service. As such, it is known to use refill bags or containers that hold a quantity of fluid and provide a pump and nozzle mechanism. These 40 refill bags are advantageous in that they are easily installed without a mess. And the dispenser can monitor usage to indicate when the refill bag is low and provide other dispenser status information.

Refill containers with identifiers such as electronic or 45 mechanical keys have been developed so as to prevent unauthorized persons from substituting inferior product into a dispensing system. Specifically, various types of mechanical or electronic keys may be used so as to associate a refill container and the fluid contained therein with a specific dis- 50 penser. Electronic keys may include, but are not limited to, magnetic sensors, optical sensors, radio frequency identification devices, and the like. In these types of dispensers, it is critical that the identifier be properly positioned or associated received in the dispenser housing. If an identification key is not properly positioned, then the refill container is not read by the dispensing system and is rendered inoperative. However, it is possible for the refill container to be operatively detected by the dispensing system but still installed in such a way that 60 the pump and nozzle mechanism jams. An improperly installed refill container that stalls or jams may cause damage to the pump actuator maintained by the refill container and/or a motor assembly and associated linkage that moves the pump actuator. An improperly installed refill container or stalled 65 pump actuator may also result in excess fluid being dispensed.

2

A pump actuator maintained by the dispenser housing or the pump and nozzle mechanism maintained by the refill container may jam or stall for any number of reasons. For example, the pump may be clogged by the fluid material from previous dispense cycles. Debris or other impediments may be blocking movement of the pump actuator or, as noted, the refill container may not be properly installed into a dispensing housing. For example, the pump can be installed underneath the actuator preventing operation of the dispenser and the refill container. In the past, the problem was solved by a user recognizing a stall condition and then the user correctly manually resetting the refill container within the dispenser housing. As such, the method of solving prior pump stalling events was unreliable and, unfortunately, the implemented fix may further damage the system. Therefore a need is present in the art for improved methods of resetting stalled pumps in electronically controlled dispensing systems.

SUMMARY OF THE INVENTION

In view of the foregoing it is a first aspect of the present invention to provide methods for resetting stalled pumps in electronically keyed dispensing systems.

Another aspect of the present invention, which shall become apparent as the detailed description proceeds, is achieved by a method for resetting a stalled pump in a fluid dispensing system, the method comprising detecting the presence of a user's hand to start a pump actuator associated with a refill container, monitoring a current sensor associated with a motor that actuates the pump actuator by rotating a motor shaft in a first direction, and reversing the motor shaft in a second direction to return the pump actuator to a starting position when the current sensor detects a predetermined level of current.

Yet another aspect of the present invention is to provide a dispensing system comprising a refill container filled with product, a housing adapted to accept said refill container, a pump maintained by either said refill container or said housing so as to dispense product from said refill container, wherein said pump has a loading position and a dispensing position, and a mechanism associated with said pump wherein said mechanism is configured to automatically return said pump to said loading position when a stall condition is detected.

These and other aspects of the present invention, as well as the advantages thereof over existing prior art forms, which will become apparent from the description to follow, are accomplished by the improvements hereinafter described and claimed.

BRIEF DESCRIPTION OF THE DRAWINGS

For a complete understanding of the objects, techniques on the refill container and that the refill container be properly 55 and structure of the invention, reference should be made to the following detailed description and accompanying drawings,

> FIG. 1 is a front perspective view of an electronically controlled dispensing system made in accordance with the concepts of the present invention;

> FIG. 2 is a schematic diagram of the electronically controlled dispensing system;

> FIG. 3 is an operational flow chart of a method for resetting a stalled pump in the dispensing system;

> FIG. 4 is an alternative embodiment of an operational flow chart of a method for resetting a stalled pump in the dispensing system;
